INTRODUCTION

The streaked horned lark (*Eremophila alpestris strigata*) is a partially migratory subspecies associated with sparsely vegetated grassland habitats (Beason 1995, Stinson 2005, Altman 2011) and is listed as threatened under the Endangered Species Act. It is also listed as endangered by the state of Washington and in Canada (Canadian Species at Risk Act 2002). The breeding range of streaked horned lark has contracted over time, with local extirpation from the northern (Puget trough, southern British Columbia, and the Washington Coast north of Grays Harbor) and southern (Rogue River Valley of Oregon) extremes of their range (Beauchesne and Cooper 2003, Stinson 2005, Altman 2011). The current breeding range includes agricultural habitats and grasslands of the Willamette Valley of Oregon, dredge deposition islands along the lower Columbia River, southern Washington coastal dune habitats, and grasslands in the Puget lowlands near Olympia and Tacoma, Washington.

Estimates of survival and fecundity from the mid-2000s indicated streaked horned lark populations in Washington were declining rapidly (Camfield et al. 2011). To provide more up to date population assessments, we developed a monitoring strategy (Pearson et al. 2015) detailing protocols for transect based monitoring that we have been implementing since 2010 on permanently occupied sites. Here we assess abundance and trends using this protocol in two geographic strata (1) Puget Sound region (sites in Pierce, Thurston, and Mason counties), and (2) Lower Columbia River and Washington coast using an analytic method that addresses issues of detectability. The goal of this monitoring effort is to assess changes in abundance and trend of this rare and declining subspecies and to provide critical information for making informed management decisions.

METHODS AND ANALYTICAL APPROACH

Lark surveys of occupied sites along the lower Columbia River, Washington coast, and southern Puget Lowlands, were conducted from 2010-2018 (Table 1) generally following the protocol of Pearson et al. (2015). All sites were visited 1-8 times per season (April 20 – July 9) and all larks detected were categorized as male, female, unknown, or young-of-the-year. In addition, observers recorded how they first detected the bird, did they see or hear it. We broadened the recommended survey window in Pearson (2015) of 1 May – 30 June to 20 April – 9 July to be more inclusive of surveys at some sites. In the future, we hope that all surveys will follow the recommended survey window. Nine sites are included “Puget” Sound region and 22 sites were included in the “River/Coast”. The majority of sites were visited three times a year, but some sites might have been visited only once (or not at all) in a any given year. Any site with only one year of data or where no birds were ever detected were not included in our analysis or figures.

A separate hierarchical binomial mixture (N-mixture) model was fit to each of the two geographic regions (Puget Lowlands and Columbia River/Coast) with four visit-level detection parameter terms for adult males, females and linear effects of wind speed for each sex (using a logit link). Detection terms are common across sites, years and first detection (audio or visual). The implication of fitting the model to the River/Coast and Puget Lowland regions separately is that sites within a region do not share information between the two regions. We feel this separation is likely given the geographic distance

between these regions and based on our information on within and between breeding season dispersal among sites and regions (Pearson et al. 2008, Wolf et al. 2019). Furthermore, inspection of the raw data suggests differences in abundance trends and detectability between the two regions, which also indicates that modelling the two regions independently is warranted (see Results).

Unclassified (sex and/or age) birds contributed to site and year specific estimates (n) with probabilities calculated from the conditional distributions from known male and female detections that were either visually detected or detected calling. Any singing bird was classified as a male with probability 1 because only males have been observed singing. Uniform priors were placed on all common terms across sites and years in a region.

The population observed at each site x year combination was assumed to have a Poisson distribution with regional mean growth rates for males and females and an autoregressive first order multiple of annual growth rate. We assess growth rate of density not abundance because it was necessary to offset density by transect length because of differences in transect length between years for a given site.

Analytical approach - In other words, for visit $l \in \{1, 2, \dots, L_{ij}\}$ to site $i \in \{1, 2, \dots, I\}$ in year $j \in \{1, 2, \dots, 9\}$ and sex $k \in \{\text{males, females}\}$, observed counts Y :

$$\begin{aligned}
 Y_{IJKL} &\sim \text{Binom}(\theta_k, n_{ijk} - u_{ijkl}) && \text{where } u_{ijkl} \text{ are unclassified birds} && (1) \\
 \text{logit}(\theta_k) &= \bar{p}_k + \beta_k^p W && \text{where } W \text{ is wind speed} && (2) \\
 n_{ijk} &\sim \text{Poisson}(e^{u_{ijk}} t_{ij}) && \text{where } t \text{ is a transect length offset term} && (3) \\
 u_{jk} &= u_{j-1k} + \ln(\lambda_k) && \text{for } j \geq 2 \text{ and a diffused prior on } u_{jk} && (4)
 \end{aligned}$$

To estimate the number of unclassified birds u_{ijkl} we first considered the likelihood of a classified bird (both adult and unknown age) being visually detected (as opposed to an aural detection), where V is the number detected visually with proportion Φ out of D detected either visually or aurally (calling only).

$$V_K \sim \text{Binom}(\Phi_k, D_k) \quad (5)$$

The standardized probabilities of an unknown-sex bird being a male given method of detection are then:

$$\Pr(\text{male}|\text{visual}) = \frac{1}{1 + \frac{\Phi f}{\Phi m}} \quad (6)$$

$$\Pr(\text{male}|\text{aural}) = \frac{1}{1 + \frac{1 - \Phi f}{1 - \Phi m}} \quad (7)$$

The probability of an unknown-sex bird being a female is the compliment:

$$\Pr(\text{female}|\text{visual}) = 1 - \Pr(\text{male}|\text{visual}) \quad (8)$$

$$\Pr(\text{female}|\text{aural}) = 1 - \Pr(\text{male}|\text{aural}) \quad (9)$$

The above gives you the same result as when Bayes rule is applied as follows:

$$\Pr(\text{sex}|\text{detection}) \propto \Pr(\text{detection}|\text{sex})\pi(\text{sex}) \quad (10)$$

The unclassified larks were multiplied by the probabilities in equations 6-9. We then multiplied the unclassified age by a uniform probability of being an adult, which produces the required quantity u_{ijkl} .

Our model was fit in JAGS 34.1 (Plummer, 2003; Appendix 1) called from R 3.5.2 (R Development Core Team 2014). Three independent chains were initialized with over-dispersed starting values were run for 7,500 iterations with the first 2,500 discarded (burn in period) and one of every ten were retained after the burn-in period for a sample of 1,500 independent draws from the posterior. Convergence of MCMC chains was checked by visual inspection of trace plots and a Gelman and Rubin's \hat{R} diagnostic.

RESULTS

For the Puget Sound region, our estimate of lambda was 0.92(0.89-0.96) for females and 1.02 (0.99-1.04) for males indicating a declining female population and a stable to increasing male population. For the Columbia River/Washington Coast, our estimate of lambda was 0.99 (0.95-1.04) for females and 0.93 (0.91-0.96) for males indicating a stable female population and a declining male population.

Table 1. Male and female detection probabilities (low/high bounds of a 95% highest posterior density interval). Note the much higher detection probability for males than females in both regions. This is not surprising given that males sing, perch on high ground and objects/rocks, and conduct flight displays.

| Probability of Detection | | | |
|--------------------------|-------|----------|-----------|
| | Mean | Lwr95HPD | Uppr95HPD |
| Puget males | 0.503 | 0.451 | 0.546 |
| Puget females | 0.278 | 0.213 | 0.340 |
| River/Coast males | 0.545 | 0.501 | 0.595 |
| River/Coast females | 0.360 | 0.291 | 0.421 |

Table 2. Influence of wind on probability of detection by sex and region. Note that there is no effect of wind on detection when the low/high bounds of the highest posterior density intervals overlap 1.0. Because the high/low bounds do not overlap zero for Puget males, this indicates a 3.2% decrease in detection probability for every 1 mph increase in wind speed.

| Probability of Detection | | | |
|--------------------------|-------|----------|-----------|
| | Mean | Lwr95HPD | Uppr95HPD |
| Puget males | 0.968 | 0.937 | 0.997 |
| Puget females | 0.987 | 0.952 | 1.023 |
| River/Coast males | 1.011 | 0.984 | 1.041 |
| River/Coast females | 1.033 | 1.002 | 1.069 |

Table 3. Mean percent of males detected audibly and females detected visually by region (low/high bounds of a 95% highest posterior density interval).

| Percent of Detections | | | |
|----------------------------|------|----------|-----------|
| | Mean | Lwr95HPD | Uppr95HPD |
| Puget males audio | 80 | 73 | 85 |
| Puget females visual | 54 | 53 | 55 |
| River/Coast males audio | 78 | 73 | 83 |
| River/Coast females visual | 55 | 54 | 56 |

DISCUSSION

The Puget Sound region female lark population is continuing to decline while the male lark population is stable to slightly increasing. On the Washington coast/Columbia River, the female population appears stable while the male population is declining.

A declining female population in the Puget Sound region is particularly worrisome given the importance of females to population recruitment and ultimately population growth. This decline was most evident on Olympia and Shelton airports (Figure 1) where little to no lark management occurred in recent years. A declining population trend on these sites may suggest the need to reevaluate our current management strategies for these sites, our overall conservation strategy for this region, and the potential need for more frequent surveys. In contrast, the Joint Base Lewis McChord (JBLM) sites appear to have relatively stable female populations and growing male populations, which may reflect a population response to ongoing management of lark habitat and human activities in nesting locations.

The declining male population on the Coast/Columbia River sites is less worrisome, unless some females are not able to find mates due to a decreasing male population. However, there is currently no evidence that females are going unmated. The only site in this region demonstrating a strong male decline was Leadbetter Point. Male and female trends on other sites in this region are relatively stable. In fact, female trends on Rice, Browns, and Miller islands appear to be increasing. Note that there are many sites on the Columbia River that are surveyed annually that currently don't have any breeding birds and therefore don't contribute information to the overall model for this region and are not included in the figures that follow.

ACKNOWLEDGEMENTS

Conducting these surveys would not be possible without the participation and contribution of numerous individuals, agencies, and organizations. Lark survey data were collected by staff from Center for Natural Lands Management (CNLM; south Puget Sound, lower Columbia River), Washington Department of Fish and Wildlife (south Puget Sound, Washington Coast), Joint Base Lewis McChord Military Base (JBLM) Fish and Wildlife Program (south Puget Sound), U.S. Fish and Wildlife Service Willapa National Wildlife Refuge, and the Shoalwater Bay Tribe. Funding to support data collection was provided by U.S Army Corps of Engineers, Joint Base Lewis McChord, and Washington Department of Fish and Wildlife. We thank land managers for providing access to occupied sites, including Brandon Palmer (Sanderson Airfield), Rudy Rudolph (Olympia Airport), and Jay Simons (Tacoma Narrows). A special thanks to all biologists participating in surveys, and to Derek Stinson, Mary Linders, William Ritchie, Michelle Tirhi, Jim Lynch, Gary Slater, Adrian Wolf, Jerrmaine Treadwell, Jessica Stokke, and Kristine Lightner for their help with data collection, management, or coordination.
